Learning Objectives

- Two-factor mixed and within-participants designs
- Focus on procedures rather than how the analysis is calculated
- How to interpret ANOVA tables and graphs
- Handling significant main effects, and simple main effects, of factors with three or more levels

Notes

Introduction

- We have now covered the three most mathematically straightforward designs:
 - 1 splitting total variability into between-group variability and within-group variability — one factor between-participants designs
 - 2 splitting within-group variability into between-participant variability and residual variability — one factor within-participants designs
 - 3 splitting between-group variability into main effect and interaction variability — 2×2 between-participants design
- There is little new to learn from analysing more complicated designs by hand

Notes

A Two-Factor Mixed Design

- Mixed design ANOVAs are particularly versatile and are often used in psychology
- These designs have at least one between-participants factor and at least one within-participants factor
- Allows the researcher to capitalise on the benefits of between- and within-participants designs within the same design
- Let's consider an example based on the Stroop task

Notes

The Stroop Task

- In the Stroop task, participants must name the ink colour of a colour word as quickly as possible:
 - on **congruent trials**, the ink colour and colour name are consistent
 - on **incongruent trials**, the ink colour and colour name are inconsistent
- Stroop effect = longer RTs for incongruent, compared to congruent, trials
- A measure of **response inhibition**

Notes

Example of A Mixed Design

- A researcher wants to know if response inhibition is impaired in patients with Schizophrenia using the Stroop task
- She employs a 2×2 mixed design:
 - patient group: healthy vs. schizophrenia
 - trial type: congruent vs. incongruent
- patient group is necessarily a between-participants factor
- trial type is a within-participants factor
- There are $2 \times 2 = 4$ conditions; **two groups** of participants (healthy vs. schizophrenia) each complete two conditions of the experiment (congruent vs. incongruent trials)

Error Terms In A Mixed-Design ANOVA

- Recall that a between-participants design uses the within-group variance as its error term
- By contrast, a within-participants design uses the residual variance as its error term
- A mixed-design ANOVA produces two error terms:
 - one for the between-participants main effect
 - one for the within-participants main effect and the interaction
- You must be careful to ensure when reporting the ANOVA that the correct degrees of freedom are read from the table

Simple Main Effects Table For Mixed-Design Stroop Experiment

- There are different approaches to testing simple main effects in mixed designs
- The simplest approach uses **pooled error terms**
- We begin by calculating the between-group variance for each simple main effect
- The calculations are identical to those used for the between-participants design (see Week 7 lecture slides)
- Each pair of simple main effects is tested for significance using the same error term (hence pooled error term approach)

Notes

Simple Main Effects Table For Mixed-Design Stroop Experiment

- The error term for testing the significance of the between-participant effects is the pooled within-group variance for the four cells
- This is calculated identically to a fully between-participants design $\{SS_{S/AB} = [Y] - [AB]; df_{S/AB} = ab(s - 1)\}$
- This is used to test the significance of the two simple main effects of the between-participants factor:
 - group at congruent
 - group at incongruent

Simple Main Effects Table For Mixed-Design Stroop Experiment

- An alternative to this approach would be to calculate a separate *t*-test for each pair of means being compared
- We would use independent-samples *t*-tests to test the simple main effects of the between-participants factor
- We would use repeated-measures *t*-tests to test the simple main effects of the within-participants factor

Simple Main Effects Table For Mixed-Design Stroop Experiment

- Once you have a graph and have calculated the simple main effects, write out the various effects as you were shown in the Week 6 lab session
- This involves reporting the F values for each simple main effect and stating the direction of the significant differences
- Once the significant effects have been identified, they must be interpreted
- Write a couple of sentences to describe the nature of the interaction (see the Week 7 lab session for an example)

Notes

What If The Design Has Three or More Levels In Either Factor?

- If the interaction is not significant, any significant main effects for factors with three or more levels will need to be followed up with planned comparisons (t -tests) or post-hoc tests (Tukey test)
- When the interaction is significant, the simple main effects for a factor with three or more levels will need to be followed up with planned comparisons or post-hoc tests
- In both circumstances, planned comparisons will often be preferable
- Make sure you use the right type (independent samples vs. repeated measures) for the effect you are testing

Calculating *F* ratios

Notes

- The book chapter in the recommended reading includes a demonstration of how to calculate the *F* ratios for a mixed design by hand
- Only study this if you are curious, it is not something you will be assessed upon
- The procedure is very similar to that used when we calculated *F* ratios for a two-factor between-participant design—it uses the same basic ratios (plus one new ratio)

A Two-Factor Fully Within-Participants Design

Notes

- A researcher wants to know if the size of the Stroop effect decreases with practice
- She employs a 2×3 fully within-participants design:
 - trial type: congruent vs. incongruent
 - block: 1 vs. 2 vs. 3
- Making *trial type* within-participants means we can establish each participant's susceptibility to the Stroop effect
- *block* must necessarily be a within-participants factor, as it requires experience with the task
- There are $2 \times 3 = 6$ conditions; a *single group* of participants completes each condition

Simple Main Effects Table For Fully Within-Participants Design Stroop Experiment

- To test the simple main effects, we calculate the between-group variances as we did in our Week 7 lecture
- The error terms to use are those from the original ANOVA table
- Thus, for the simple main effects of factor *A* (trial type) at *B*₁, *B*₂, and *B*₃ the error term for testing factor *A* could be used (*Error A × P*)
- For the simple main effects of factor *B* (block) at *A*₁ and *A*₂ the error term for testing factor *B* could be used (*Error B × P*)

Follow Up Tests For Simple Main effects Of Factors With Three Or More Levels

- In this instance, one of the simple main effects of our factor with three levels (block at incongruent) was significant
- We therefore need to perform follow up tests (planned comparisons or post-hoc tests) to determine where the differences are located
- I recommend using planned comparisons where possible
- We will evaluate the simple main effect of block at incongruent trials by performing two repeated-measures t -tests comparing block 1 vs. block 2 and block 2 vs. block 3 (i.e., planned comparisons)

Notes

Calculating F ratios

- The book chapter in the recommended reading includes a demonstration of how to calculate the F ratios for a within-participants design by hand
- Only study this if you are curious, it is not something you will be assessed upon
- The procedure is very similar to that used when we calculated F ratios for a two-factor between-participant design—it uses the same basic ratios (plus one new ratio)

Notes

A Note On The Sphericity Assumption

- The sphericity assumption extends to within-participants factorial designs with factors containing three or more levels
- It also applies to within-participant factors with three or more levels in mixed designs
- R will apply the Greenhouse and Geisser correction if the sphericity assumption is violated
- We'll cover this in more detail in next week's lab
